

There are two players, sender and receiver, and a state of nature $q \sim U[0, 1]$ which is known to the sender but not to the receiver. Let g denote the density of q . The sender and receiver have preferences over actions $U(q, A) = -(A - q)^2$. Let \mathcal{M} denote the set of all non-decreasing functions from $[0, 1]$ to $[0, 1]$. Let $m \in \mathcal{M}$ be a message function. Let $Q(\tilde{m})$ denote the set of all $q \in [0, 1]$ such that for some $e \in [-\bar{\epsilon}, \bar{\epsilon}]$, $\tilde{m} = m(q) + e$. Finally, put $q_+(\tilde{m}) \equiv \sup Q(\tilde{m})$, and $q_-(\tilde{m}) \equiv \inf Q(\tilde{m})$. Suppose that the receiver receives the message $\tilde{m} \in [-\bar{\epsilon}, 1 + \bar{\epsilon}]$. $q|\tilde{m}$ has support $[q_-(\tilde{m}), q_+(\tilde{m})]$, and

$$g(q|\tilde{m}) = \frac{f_e(\tilde{m} - m(q))\mathbf{1}_{0 \leq q \leq 1}}{\int_0^1 f_e(\tilde{m} - m(t))\mathbf{1}_{0 \leq t \leq 1} dt}. \quad (1)$$

Her optimal action is

$$A(\tilde{m}) \equiv \operatorname{argmin}_a \int_{q_-(\tilde{m})}^{q_+(\tilde{m})} (q - a)^2 g(q|\tilde{m}) = \int_{q_-(\tilde{m})}^{q_+(\tilde{m})} q g(q|\tilde{m}) \quad (2)$$

As it will appear often, let the cost functional $C : \mathcal{M} \rightarrow \mathbb{R}$ be given by

$$C[m] \equiv \int_0^1 \int_{-\bar{\epsilon}}^{\bar{\epsilon}} (q - A(m(q) + e))^2 f_e(e) de dq. \quad (3)$$

The *sender's problem* is to choose a message $m \in \mathcal{M}$ that minimizes C . A change of variables and an application of Fubini's Theorem yeild

$$C[m] = \int_0^1 \int_{m(q)-\bar{\epsilon}}^{m(q)+\bar{\epsilon}} (q - A(\tilde{m}))^2 f_e(\tilde{m} - m(q)) d\tilde{m} dq \quad (4)$$

$$= \int_{-\bar{\epsilon}}^{1+\bar{\epsilon}} \int_{q_-(\tilde{m})}^{q_+(\tilde{m})} (q - A(\tilde{m}))^2 f_e(\tilde{m} - m(q)) dq d\tilde{m}. \quad (5)$$

Finally, note that $\int_{-\bar{\epsilon}}^{1+\bar{\epsilon}} \int_{q_-(\tilde{m})}^{q_+(\tilde{m})} dq d\tilde{m} = \int_0^1 \int_{m(q)-\bar{\epsilon}}^{m(q)+\bar{\epsilon}} d\tilde{m} dq = 2\bar{\epsilon}$.

Proposition 1. *If the error is uniform, then the discrete message function is optimal.*

Proof. $f_e(e) = \frac{1}{2\bar{\epsilon}} \mathbf{1}_{-\bar{\epsilon} \leq e \leq \bar{\epsilon}}$, $g(q|\tilde{m}) = \frac{1}{q_+(\tilde{m}) - q_-(\tilde{m})} \mathbf{1}_{q_-(\tilde{m}) \leq q \leq q_+(\tilde{m})}$, $A(\tilde{m}) = \frac{q_+(\tilde{m}) + q_-(\tilde{m})}{2}$, and

$$C[m] = \frac{1}{2\bar{\epsilon}} \int_{-\bar{\epsilon}}^{1+\bar{\epsilon}} \left[\frac{2}{3} \left(\frac{q_+(\tilde{m}) - q_-(\tilde{m})}{2} \right)^3 \right] d\tilde{m}. \quad (6)$$

Under m_d , $q_+(\tilde{m}) - q_-(\tilde{m}) = \frac{2\bar{\epsilon}}{2\bar{\epsilon}+1}$, and hence $C[m_d] = \frac{1}{3} \left(\frac{\bar{\epsilon}}{1+2\bar{\epsilon}} \right)^2$. Let $m \in \mathcal{M}$.

$$C[m] = \frac{1+2\bar{\epsilon}}{2\bar{\epsilon}} \int_{-\bar{\epsilon}}^{1+\bar{\epsilon}} \left[\frac{2}{3} \left(\frac{q_+(\tilde{m}) - q_-(\tilde{m})}{2} \right)^3 \right] \cdot \frac{d\tilde{m}}{1+2\bar{\epsilon}} \quad (7)$$

$$\geq \frac{1+2\bar{\epsilon}}{2\bar{\epsilon}} \cdot \frac{2}{3} \left(\int_{-\bar{\epsilon}}^{1+\bar{\epsilon}} \left(\frac{q_+(\tilde{m}) - q_-(\tilde{m})}{2} \right) \cdot \frac{d\tilde{m}}{1+2\bar{\epsilon}} \right)^3 \quad (8)$$

$$= \frac{1+2\bar{\epsilon}}{3\bar{\epsilon}} \left(\frac{\bar{\epsilon}}{1+2\bar{\epsilon}} \right)^3 \quad (9)$$

$$= C[m_d], \quad (10)$$

where the second line follows by Jensen's inequality. ■

Proposition 2. *If the error is not uniform and if its variance is sufficiently small ($< C[m_d]/(1+2\bar{\epsilon})$), then the optimal message function is not discrete.*

Proof. Put $m_i(q) \equiv q$. Under m_i , we have that $q_-(\tilde{m}) = \tilde{m} - \bar{\epsilon}$, $q_+(\tilde{m}) = \tilde{m} + \bar{\epsilon}$, and $g(q|\tilde{m}) = f_e(\tilde{m} - m(q))$. Put $\delta \equiv \tilde{m} - m_i(q)$. $A(\tilde{m}) = \tilde{m} - \int_{-\bar{\epsilon}}^{\bar{\epsilon}} \delta f_e(\delta) d\delta$, and

$$C[m_i] = \int_{-\bar{\epsilon}}^{1+\bar{\epsilon}} \int_{-\bar{\epsilon}}^{\bar{\epsilon}} \left(\delta - \int_{-\bar{\epsilon}}^{\bar{\epsilon}} \delta' f_e(\delta') d\delta' \right)^2 f_e(\delta) d\delta d\tilde{m} \leq C[m_d] \quad (11)$$

from which the result obtains. ■
